# A Real Time based Physiological Classifier for Leaf Recognition 

Avinash Kranti Pradhan ${ }^{1}$, Pratikshya Mohanty ${ }^{2}$, Shreetam Behera ${ }^{3}$

#### Abstract

Plants are everywhere around us. They possess many vital properties necessary for human survival. The lack of knowledge about plants and the global shortage of agricultural experts have inspired the need to create automation in the process of identification of leaves. The recognition of plants can be done by considering the basic physiological features of leaves. This paper has proposed a real time based identification system for recognising different varieties of leaves along with important details about the plant. Here the leaf image is preprocessed from which different features are extracted and are fed to a physiological based recognition system for leaf identification. This is a simple approach which gives accurate results under any conditions.

## Keywords

Feature extraction, Physiological features, Pre-process, Physiological based recognition system.

## 1. Introduction

Plants occupy a major portion of our ecosystem. They are a source of oxygen, food, fuel, raw materials, shelter, clothing, medicines etc. They play a pivotal role for the survival of different living creatures and maintain a balance in the ecosystem. Some plants possess medicinal property while some other is poisonous. Even there are many varieties of plants which are at the verge of extinction. Thus it is important to maintain a database which will prevent the plants from being extinct and will serve as a source of knowledge base, carrying significant information about the plant.

[^0]In this study, a real time based leaf recognition system is proposed to identify different varieties of leaves based on their basic physiological features. The extracted features form a database, which are fed to a physiological classifier for recognition of leaves.

Several researchers have developed many algorithms for the recognition of different plant species. In [1], a plant identification system has been created that used features such as slimness ratio, roundness ratio, solidity, invariant moments and features to represent leaf dent and vein. This system was able to recognize six kinds of different plants.

A system has been designed and implemented in which different geometric and morphological features are extracted from plant leaves [2]. This system uses image processing based algorithms and machine learning techniques.

The concept of computer vision was applied in the field of agriculture mainly for non- destructive testing of leaves, flowers, fruits and vegetables [3], [4]. In [5], a novel technique has been proposed which uses color features to segregate rotten vegetables from a mixture of fresh and rotten ones. Two color textures are taken into consideration i.e. green and yellow. [6] Presents a paper on detection of defects in fruits by feature extraction. The algorithm has been designed in such a way that the weights for different features are being calculated.

A method has been implemented towards identification of leaves using feature extraction and Probabilistic neural network (PNN) where the extracted features are fed as input to PNN. This algorithm could recognize 32 different kinds of plants [7]. In [8], an approach has been proposed to implement leaf recognition system which uses leaf vein and shape as the basis for classification. The main vein and the frequency domain data have been taken into consideration using Fast Fourier Transform. A methodology has been developed for the classification of betel leaves which uses both feature extraction and application of machine learning technique [9]. Paper [10] presents a method for medicinal plants identification based on its leaf features such as area and edge.

## 2. Proposed Methodology

### 2.1. Image Acquisition

The real time image of leaves has been captured using a webcam (Vimicro USB2.0 UVC PC Camera). The images are taken from the top with white background.

12 different varieties of leaves are taken. The samples of leaf images are shown in Fig.1.

Fig.1: Leaf samples (a) Betel (b) Hibiscus (c) Jackfruit (d) Tagar (e) Basil (f) Brahmi (g) Neem (h) Jasmine (i) Rose (j) Money plant (k) Mango (l) Yellow Oleander

### 2.2. Image Pre-processing

2.2.1. Conversion of RGB to Gray scale image

The RGB image of the leaf is converted to gray scale image by using the following formula:
Gray scale image $=$ red component $* 0.3+$ green component $* 0.59+$ blue component $* 0.11$
The gray scale image is then, converted to black and white.

### 2.2.2. Application of Max filter

Max filtering is applied for noise reduction and making the image smooth.

Fig.2: Pre-processing of leaf image

### 2.3. Feature Extraction

26 leaves of each class are taken and the five basic physiological features i.e. perimeter, area, length, width and aspect ratio are extracted as follows:

### 2.3.1. Area

The leaf area is calculated by counting the total number of pixels in the region of leaf. The calculated value is divided by 100 to obtain a finite value.
Algorithm for calculating area:
Step 1: Start
Step 2: Acquire the real time image of the leaf
Step 3: Convert color image to gray scale
Step 4: Convert gray scale image to black and white
Step 5: Count the number of pixels in the leaf region
Step 6: Store the value in a database
Step 7: Stop

### 2.3.2. Perimeter

The perimeter of a leaf is calculated by counting the number of pixels in the edge of the leaf. Sobel operator is used for edge detection.

Algorithm for calculating the perimeter:
Step 1: Start
Step 2: Acquire the real time image of the leaf

Step 3: Convert color image to gray scale Step 4: Convert gray scale image to binary Step 5: Apply Sobel operator and find its edge Step 6: Count the number of pixels on the edge Step 7: Store the value in a database Step 8: Stop

### 2.3.3. Length

The distance between the two ends of the main vein of leaf is called its length.

### 2.3.4. Width

The leaf width is defined as the distance between the intersection point with length at the centroid and its opposite side on the margin of the leaf.

### 2.3.5. Aspect ratio

It is the ratio of leaf length to leaf width. The obtained value is multiplied by 1000 to get a whole number instead of fraction.
Aspect ratio= Length of leaf/ Width of leaf

### 2.4. Database Creation

The five physiological features of 26 leaves of each individual class are stored in a database. The flow chart of feature database creation is shown in Fig.3.

Fig.3: Feature Database Creation
The feature database of different class of leaves is shown:

### 2.5. Physiological based classifier

Experimentally the maximum and minimum values of each feature of different class of leaves are found from the database and a range is defined for each feature for a particular class of leaf.When a real time test image is captured using a webcam, it is preprocessed and its features are extracted. These extracted features are compared with the different range defined for each feature in the physiological classifier. The leaves, whose features match with the defined range, are identified and detail information about the particular plant such as its scientific name, uses etc. is provided.

If an image of leaf is captured which is not there in the database, its features would not match with any of the defined range and hence the system will show "Leaf is not recognized".

Fig.4: Testing using Physiological classifier

## 3. Results

When a real time image of a leaf from any of the above 12 varieties is taken for identification purpose, its features are extracted and are compared with the defined range. The system is thus, able to recognize the particular leaf. Since the dataset consists of 26 leaves from each class, it is sufficient enough to study the variation in leaf features. If the particular leaf is not present in the dataset, the system would not be able to recognize the leaf.

## 4. Conclusion

This paper introduces a novel approach towards identification of leaves using physiological classifier. The method is implemented using real time images of leaves in MATLAB platform version 7.0. It has been found that the proposed system reduces time since there is no need to train the system unlike other complex algorithms. The results are found to be accurate and the accuracy of the system increases
with increase in the number of features. Thus, the proposed algorithm is simple, cheap, fast in execution and easy to implement.
