### Abstract

*Ugali is a thick porridge that is one of the popular staple foods in East Africa. Traditional methods of ugali preparation, cooking, and consumption are described. Firewood has been used as the primary energy source followed by charcoal. In East Africa, electricity grids have expanded and reached a wider network, which has opened opportunities for electric cooking to domestic consumers, especially in urban that was previously dominated by charcoal, which is in scarce supply due to government regulations on environmental conservation. In this project, the smart ugali cooker was designed and developed to automate the process of cooking ugali in households which is faster, safer, and healthier. The smart Ugali cooker is an automated kitchen appliance designed to boil the mixture of water and maize flour into a dough mixture referred to as ugali. It consists of a driving motor, stirrer, flour dispenser, heat source, a cooking pan, a temperature sensor that measures the temperature of the boiling water in the pan, and the control system (Arduino board). The device has basic units that are a dispenser, stirring unit, electronic control unit, pan, and electric heater. These units were fabricated and integrated to form the complete cooking device. Thereafter, the Arduino board was programmed to control the cooking process. Cooking experiments were conducted, on the cooking duration and the texture of ugali based on water to flour ratio. The results showed that ugali was cooked after ten minutes and the quality was good for consumption. In recommendation, the rightful flour to water ratio must be applied to obtain the desired texture of ugali.*

### Keywords

*Arduino, Control system, Stirrer, Ugali.*

## 1. Introduction

Ugali is a staple food delicacy in the East Africa region, which is made from maize flour and water with a heating source. It is cooked into a dough-like consistency then served with greens or stew [1]. The desired ratio of flour and water for making ugali is approximately thirty percent (30% w/v) [2]. Water is boiled in a cooking pan, and then about thirty percent (30%) of flour is added. Continuous heating is applied without any interruption, to resume the boiling. The rest of the flour is added while stirring until it becomes a thick paste. The stirring will be done for the next seven up to ten minutes [3]. There are several methods for testing the ugali texture, one of them is the wall-test, where a slice of the cooked ugali is thrown to a wall. If the ugali is well cooked, it will not stick on the wall, otherwise, it is undercooked.

The texture of ugali can be determined by simply pressing a finger in the cooked ugali. The pressed finger when released should not stick or contain any ugali that is the correct texture [3]. Ugali which is not cooked well will disintegrate and sticks to the hand. As [4] stated that a good ugali should not contain any lumps. Ugali is best served while still hot, usually within an hour after cooking.

The problem that has been identified with the conventional method of cooking, is that sometimes ugali gets undercooked or overcooked, thus compromising on the consistency and nutrients. Another major concern was exposure to high temperatures which leads to health deterioration. Smoke exposure leads to health complications thus cooking devices that are efficient and can address those challenges needed to be developed [5]. Besides, the benefit of electronic cooking, household clean air, less cooking time [6], and overutilization of fuel from the wood have major effects; reduction in trees,

\*Author for correspondence

biodiversity, accelerating global warming [7], and pollution emissions which increase deforestation [8]. According to [9] cooking with electricity is reducing explosions thus ranked as one of the safest sources of cooking with exposure to a heat source to below level.

The main objective of this project is to develop the smart ugali cooker which is faster, safer, and healthier. To achieve this main objective, the project included the following specific objectives:

1. To design and develop a smart ugali cooker.
2. To design the stirring unit of the ugali cooker.
3. To design the heating and control system of the ugali cooker.

## 2.Literature review

The existing solutions to some of the identified problems are the nsima (ugali) cooker in Malawi for electric cooking and the gwatamatic in Zimbabwe, which is deployed in hotels, schools for a wide use of the application due to its big size and energy utilization.

The gwatamatic was for industry large applications but not suitable for home cooking because of the size, high electricity requirement, and the cost of purchase, running expenses, and maintenance. In contrast, the nshima cooker is smaller in size, patented, prototype suitable for nshima, and it was not rolled out for consumer use. These are the main gaps that the project identified, which the smart ugali cooker has attempted to address.

Top-Lit Up-Draft (TLUD) cooking method, the 2018 study of consumption was conducted to identify how ugali was prepared and the challenges encountered by the cook in Kenya. The results revealed that seven out of fifteen observations that the ugali was cooked [10]. During the cooking process, ugali requires stirring continuously, thus it forces the cook to always stand and bend to maintain control of the pot while stirring. Another challenge on cooking that the author pointed out was the pot sometimes slipped from the heat source, which made the cook to change positions. Therefore, the TLUD gasifier stove was introduced to solve those challenges, it resulted in control and stability for the cook, especially when the ugali was getting harder and thicker during the cooking process [11]. The impact of the introduced method or solution (TLUD stove) to the user was portability and reduced firewood consumption. So, the portability of the device provided convenience to

cooks in terms of where they wanted to cook, its convenience since cooks could multitask [10].

The TLUD cooking technique was able to solve the portability for choosing the location for cooking and the stability of the cooking pot on the stove, which enable the cook to be comfortable while cooking. But for the current trend of science and technology, people are busy with many tasks to attend to more chores like attending to children, going through their children's homework, while tired with the day's tasks. Therefore, they still need more improvement in cooking and more automation so that they can easily manage their time.

Even though ugali is most frequently consumed in east Africa, the challenge of preparation in the homes or hotels results in inconsistency and low quality [12]. The smart Ugali cooker is an automated kitchen appliance designed to boil the mixture of water and maize flour into a dough mixture referred to as ugali. It consists of a driving motor, stirrer, flour dispenser, heat source, a cooking pan, a temperature sensor to measure the temperature of the boiling water in the pan, and the arduino board, which is the control system. The project aims to automate the conventional way of cooking ugali, through cost-effective means by developing a smart ugali electric cooker. The main target and beneficiaries of the project are the home consumers. The scope of the project was to design and develop an automated device for cooking ugali.

The project argues that the smart ugali cooker has the prospect to change the cooking methods and simplify lifestyle, especially in the urban population in the East African market just like the rice cookers transformed cooking markets. A study conducted by [13] discovered that more Tanzanians are embracing cooking with electricity by using appliances that utilize energy more efficiently. The ugali cooker was designed to be faster and convenient in some ways that were not possible before. It consumes less energy compared to charcoal or firewood while it produces more consistency and reliability. The East African market has adopted this new technology through the electrical kitchen and consumer home electronics. The smart ugali cooker combines an electric heater, a pan, motorized stirring, and a fully automated control system. As a result, it increases the consistency and speed of cooking which is convenient for modern homes [14].

### 3. Materials and methods

#### 3.1 Specification and design

The device has basic units that are a dispenser, stirring unit, electronic control unit, pan, and electric heater. The smart ugali cooker is designed for home; the model cooks 0.5kg of maize flour. It is equipped with a temperature sensor, which keeps the ugali optimal temperature for serving without over-cooking it. It uses induction heating, the heater directly warming the pan. This can improve energy efficiency. The pan is made up of stainless steel, while the flour dispenser is made of plastic that withstands the heater temperatures, with a capacity that holds 0.5kg of maize flour.

##### 3.1.1 Dispenser

A container that holds and feeds maize flour into the pan after water is boiled, which is accomplished by monitoring through temperature sensor DS18B20 and releasing flour by opening using the servo motor which is triggered by the control unit.

##### 3.1.2 Dispenser features

The dispenser is equipped with a hole and lid at the bottom that will release the maize flour by opening the lid using the servo motor.

##### 3.1.3 DS18B20 sensor specifications

Programmable Digital Temperature Sensor, Communicates using the 1-Wire method, Operating voltage: 3V to 5V, Temperature Range: -55°C to +125°C, Accuracy: ±0.5°C.

##### 3.1.4 Stirring unit

This is a metal blade for mixing water and maize flour to the appropriate texture, which will be

triggered after water, is boiled and flour released. The stirring unit is powered by an electric DC (Direct Current) motor and stirring blades embedded on the motor. A control unit through a relay switch will turn on the motor after water is boiled and flour released. Specifications of the electric motor have been presented in *Table 1*.

##### 3.1.5 Electronic control unit

The control unit (an Arduino board), uses stimulus from the temperature sensor to control the cooking cycle. The device is turned on, the control unit switches on the heating element through the relay switch, monitors the temperature of the boiling water through a temperature sensor, and when the water boils, it triggers pouring of maize flour from the dispenser into the pan and stirring by turning on the stirring system through the relay switch. Then the stirring of the mixture will continue gradually for three minutes. Finally, turn off the cooker and alert the user by a brief sound of a buzzer and displaying a message on the LCD (Liquid Crystal Display) screen.

##### 3.1.6 The pan

This is a cooking container that holds Ugali. The pan is made from stainless steel, for durability, rust-free, and a good conductor of heat, which helps in supply the heat evenly and faster cooking cycle. The dimensions of the pan are diameter 21cm, depth 16cm, which can hold up to a maximum of 5.5litres of water.

### 3.2 Implementation

The project was implemented through the following steps;

1. Fabrication of mechanical parts.
2. Control unit implementation.
3. Programming of the Arduino board.
4. Device Integration.
5. Testing.

#### 3.2.1 Fabrication of mechanical parts

After the design process, the mechanical parts were fabricated using steel iron frame and plastic as per the specifications, the base structure holding the heater and pan, a mechanical arm holding the motor, dispenser, and control.

#### 3.2.2 Control unit

The control unit is powered by an Arduino microcontroller board, which controls the cooking cycle. Firstly, the Arduino triggers the relay to turn on the heater that boils the water to the required temperature which is measured through the temperature sensor. It then triggers the servo motor to open the dispenser lid to release the flour into the cooking pan. After, it triggers the stirring unit to stir the mixture for three minutes and finally turns off the heater, stirring unit, then triggers the buzzer as well as display a “Ready message” on the LCD screen.

#### 3.2.3 Programming of Arduino board

The Arduino IDE (Integrated Development Environment) supports languages such as C and C++ using special rules of code structuring. The Arduino IDE supplies a software library that provides many common input and output procedures. The cooking process was implemented through the following methods in C programming language: Temperature sensor reading with library declaration, whereby signal wire was connected into pin 2 on the Arduino, then passes a one-wire reference to ‘Dallas Temperature’. Relay switches for motor and heater were declared in Pin 3 and Pin 4 respectively. LCD pins (RS, E, D4, D5, D6, D7) were configured from pin 8 to 13 respectively. The buzzer pin was declared and connected to pin A0 (Digital pin 14); The arduino pin mode for the heater, motor, and buzzer was set to output; The servo was attached to Pin 6 to initiate flour release through open flour method, and closing through close flour method; The Arduino was programmed to turn off first the motor and buzzer through motor off and buzzer off methods respectively, immediately after the device is turned on and then turn on the heater through the heater on

the method. After the water was boiled, flour was released from the flour dispenser through the servo motor, and the DC motor was switched on to stir the flour through the motor on the method. After the cooking process, the Arduino was programmed to turn off the heater and DC motor through the heater off and motor off methods respectively. Finally, alert the user by turning on the buzzer and display a message to the user through the LCD screen that; “Ugali is ready”.

#### 3.2.4 Device configuration

The L-shaped holding frame structure, pan, heater, dispenser, DC motor, and control unit were integrated to allow them to interact and interoperate to make up the whole smart cooker.

The L-shape holding structure was manufactured to hold the other parts of the device. These parts include the heater which was mounted at the bottom base of the structure to heat the pan which was placed on top of the heater. The dispenser was mounted at the upper side of the vertical L-shaped structure, to enable flour release into the pan. The structure of the DC motor was designed in such a way that it has to be placed at the top with the stirrer facing downwards to enable the mixing of the flour in the pan. And finally, the control box was placed at the top of the DC motor structure which controls the whole cooking process.

#### 3.2.5 Testing

Different test procedures were carried out right from program code to the working/functioning of the system, to get the required standard feasible for the project. This included a temperature sensor measuring the accurate temperature as required. This was accomplished by comparing the temperature at room temperature and moderate boiling temperature with a thermometer. Dispenser releasing flour as required and the correctness of the servo motor when releasing the flour, which was accomplished by a correct rotation of the servo motor opening to 90 degrees to allow a maximum opening for the flour to be released. The timing of the stirrer at the start when the water was boiled and the flour released, and the stirrer was able to stop after the cooking time elapsed.

**Figure 5** Pictorial representations of the cooking process

#### 4.Results

Cooking experiments were conducted using the smart ugali cooker loaded with 500g maize flour and 2000ml of water. The ugali was taken out after ten minutes and it was found to be well cooked. The overall time of cooking was maintained within a range of ten to fourteen minutes. A time of fewer than five minutes resulted in undercooking and more than fifteen minutes caused overcooking. The quality of ugali was determined by its texture, whereby several simple tests were carried out to assess the cooked ugali's texture. The 'wall-test', was used to know if the ugali was cooked properly, by throwing a slice of the ugali on the wall. Ugali which stack was considered to be not well-cooked. On the other hand, if it fell, it was considered to be well cooked [3]. The overall texture of the ugali cooked was found to be of good quality.

#### 5.Discussion

Figure 5, shows a representation of a cooking process whereby, a picture of the smart ugali cooker prototype as defined in (Figure 5, A); water was poured into the pan and left to boil (Figure 5, B); After reaching the defined boiling point, flour was released into the pan in (Figure 5, C), and left to boil for 0.5 minutes (Figure 5, D); Then after 0.5 minutes, the process of flour mixing took place (Figure 5, E) and ugali was made ready and removed out of the pan (Figure 5, F), and ready to be served (Figure 5, G).

The smart ugali cooker proved to be faster and convenient with less energy consumption compared to charcoal or firewood. This improves the cooking environment of most homes. The cooker was fully automated from the boiling of water up to the time when the ugali was ready. User interaction involved loading the flour into the dispenser and water into the cooking pan as well as turning on the device. In comparison along with the results provided, the ugali cooker was able to solve the existing gap that other methods were not able to solve in the following ways;-

- In terms of size, the smart ugali cooker was relatively small and convenient as compared to automatic cooker which was designed for large scale uses.
- The cooking time was reduced to a lesser time in comparison with the Top-Lit Up-Draft (TLUD) cooking method and other local methods of cooking.
- There was no human intervention during the cooking process in the smart cooker as compared to the TLUD cooking method.
- The traditional ways of preparing ugali majorly involve direct exposure to heat since human interaction is the major activity whereas the smart ugali cooker does not expose the user to direct heat.

#### 5.1Limitations

The limitations of the study during the development of the smart ugali cooker are the following;-

1. Fabrications of some of the mechanical parts, in terms of design, cost, and reliability.
2. Availability of the correct specification of an electric motor with the required working load.
3. The heating source dissipated more heat than initially designed.

## 6. Conclusion and future work

The design and development of a smart ugali cooker for a domestic cooking application have been presented, with the predicted and actual performance of the device. The cooking test results showed that the cooker was always capable of cooking food equivalent to 500g of flour at a time, within the expected length of time. This aligns with the main focus which aimed to design and develop a cooker with consideration of labor economy, and energy cost savings. The device is simple to use and it does not require any special skills to get consistent results.

After the successful implementation of the first version of the smart ugali cooker, and through the challenges encountered, the following can be considered as future work;

- To improved design on the stirring unit
- To reduce the size of the device for portability.
- Also, the device can even be controlled remotely via a mobile phone, initiating the cooking process.

## Acknowledgment

We are so grateful to thank CENIT@EA (Center of Excellence for ICT in East Africa) for the scholarship and project funding, the immediate project supervisors Dr. Mussa Ally, Dr. Michael Kisangiri, and Dr. Neema Mduma for their continued guidance and support throughout the project.

## Conflicts of interest

The authors have no conflicts of interest to declare.
