### Abstract

*This paper presents an improved mayfly algorithm (IMA) for identifying the optimum control settings of optimal power flow problem in regulated electric power networks. IMA is the improved version of the mayfly algorithm (MA) by implementing simulated binary crossover and polynomial mutation instead of arithmetic crossover and normal distribution mutation operators in MA. The attributes of genetic algorithm (GA), particle swarm optimization (PSO), and firefly algorithm (FA) are taken into account in IMA. Single objective functions such as total fuel cost, total active power losses, total voltage variation, and voltage stability index (VSI) are used to assess the performance of the algorithms. The optimal solution of each objective function is evaluated by representing the test systems in MATPOWER. The results of IMA are compared with GA, PSO, and MA. Investigations based on the optimal solution, convergence characteristics, and statistical measures of the solution ensure IMA's superiority over alternative algorithms. The performance of the algorithms is evaluated by simulation of the IEEE-30 bus system, 62-bus Indian utility system and the IEEE-118 bus system. For IEEE-30 bus system the optimal solutions of the objective functions are 802.1448 \$/hr, 3.6487 MW, 0.5279 pu and 0.1247. In case of 62-bus utility system the optimal solutions of the objective functions are 13305.4267 \$/hr, 73.8746 MW, 0.8049 pu and 0.0986. For IEEE-118 bus system the optimal solutions of the objective functions are 129611.5389 \$/hr, 76.5261 MW, 0.8632 pu and 0.0611 are obtained by implementing IMA.*

### Keywords

*Genetic algorithm, Improved mayfly algorithm, OPF, Polynomial mutation, Simulated binary crossover.*

### 1. Introduction

The optimal power flow (OPF) problem is mathematically formulated by Carpentier [1]. The OPF is framed as the most important power system optimization problem. Power engineers can carry out the studies that are required for further planning and operation of the existing power systems with the integration of renewable energy sources. Mathematically, the OPF is represented by non-linear static equations. Solving the non-linear static equations gives a solution that describes the performance of power system networks. The solution of OPF problem is to obtain optimal values of design variables that optimize the objective function subjected to a set of constraints. The state variables describe the performance of the system at every step.

The control variables control the systems to evolve from one step to the next step [2]. The objective functions are total fuel cost (TFC), total active power losses (TAPL), total voltage deviation (TVD), and voltage stability limit (VSI). TFC reduces the overall cost of generation. TAPL reduces transmission line losses, thereby increasing the power transfer capabilities of transmission lines. TVD minimises voltage variation in the load bus. VSI enhances stability by preventing the system from voltage collapse. The design variables are active power and voltage magnitudes at generators, transformer tap setting ratio and VAR compensators. The solution of optimization problems is achieved through the implementation of the following steps [3]: (i) Select the control and state variables, (ii) Frame the objective functions and constraints, (iii) Assign limits to the selected variables, (iv) Choose a suitable algorithm to optimize the problem, (v) Find the optimal solution to the problem.

\*Author for correspondence

The OPF problem sets the goals as minimization of fuel cost, minimization of active power losses, minimization of voltage deviation and minimization of voltage stability limit. These goals are achieved by adapting improved mayfly algorithm (IMA) to OPF problem. The solution gives optimal values for the design variables. IMA is chosen to evaluate the results of OPF in the standard IEEE-30 bus system, IEEE-118 bus system and the practical 62-bus Indian utility system using MATPOWER with MATLAB. The results obtained by IMA illustrate the competition with MA, particle swarm optimization (PSO) and genetic algorithm (GA). The major contribution is implementing the simulated binary crossover operator and polynomial mutation operator in MA for OPF problem.

This paper is organized as: Section-1 is started with the origin and significance of OPF, section-2 with literature review of OPF, formulation of OPF problem with four single objective functions including constraints in section-3. It also describes about the attributes of IMA. The performances of various algorithms are reported in section-4. Section-5 discusses the analysis of results in discussions and section-6 concludes the research work through the findings.

## 2.Literature review

OPF problem is solved by conventional methods such as gradient methods [4], NR method [5], sequential linear programming method [6], sequential quadratic programming [7], linear and non-linear interior point methods [8], semi-definite programming [9] and so on. The solution of OPF problem obtained by implementing conventional methods gives only one solution that may struck within the local space [10].

In order to obtain a solution in global search space, meta-heuristic techniques such as an improved heap optimization algorithm (IHOA) is proposed by Shaheen et al. (2022) to solve optimization problem [11]. Dash et al. (2022) proposed boundary assigned animal migration optimization algorithm (BAAMOA) [12] to solve OPF problem.

Kahraman et al. (2021) implemented manta ray foraging optimization (MRFO) [13], Phanden et al. (2021) implemented modified ant colony optimization (MACO) [14] are used to solve optimization problem in power system. Naderi et al. (2021) implemented fuzzy adaptive hybrid self-adaptive PSO and DE algorithm (FAHSA-PSODEA) to handle multiple objective functions and non-

convex OPF problem [15]. Su et al. (2021) proposed deep learning algorithm that is being implemented through an unsupervised deep belief network (DBN) to obtain the optimal values of generators and transient stability index [16]. Meng et al. (2021) implemented crossover grey wolf optimizer (CS-GWO) by introducing horizontal crossover in the grey wolves' chasing mechanism to solve OPF problem for IEEE-30 bus and IEEE-118 bus [17] system. Li et al. (2021) presented adaptive constraint DE (ACDE) that reduces fuel cost by 3.76% when compared with modified pigeon inspired optimization through constraint objective sorting rule (MPIO-COSR) [18]. Rahman et al. (2021) developed a learning augmented approach (LAA) based on machine learning to solve AC OPF problem in 500 and 4918 bus test systems [19]. Karimulla et al. (2021) proposed enhanced sine cosine algorithm (ESCA) to reduce the objective functions such as total production cost and losses, to improve VSI and to reduce the emission level in the IEEE-30 bus system [20]. Aziz et al. (2021) implemented an artificial immune system (AIS) for reducing system losses and voltage deviation through optimal placement and sizing of static Var compensator [21].

Gungor et al. (2020) proposed tree seed algorithm (TSA) [22], Diab et al. (2020) implemented coyote optimization algorithm (COA) [23], Hussein et al. (2020) proposed cuttle fish algorithm (CFA) [24] and so on. are used to obtain the best solution of optimization problem. Chen et al. (2020) implemented MPIO to solve single and multi-objective functions as combination of fuel cost, active power loss, fuel cost combined with valve point [25]. Warid (2020) proposed an adaptive multiple team's perturbation guided jaya (AMTPG-Jaya) algorithm to solve OPF problem [26]. Srilakshmi et al. (2020) implemented most valued player algorithm (MVPA) to solve OPF problem in IEEE-30 and IEEE-57 bus systems [27].

Nguyen (2019) proposed novel improved social spider optimization algorithm (NISSOA) for optimizing fuel cost, losses, emission, bus voltage deviations, and L-index in IEEE-30 bus, IEEE-57 bus and IEEE-118 bus test systems [28]. Biswas et al. (2018) proposed DE algorithm integrated with constraint management techniques [29], Attia et al. (2018) presented novel sine cosine algorithm (NSCA) [30], Shaha et al. (2017) described water evaporation algorithm (WEA) [31], Mukherjee and Mukherjee (2016) proposed novel oppositional krill herd algorithm (NOKHA) to solve OPF problem

[32]. Each technique has own individual benefits and drawbacks to achieve the best solution for the particular problem. These artificial techniques are categorized based on the social behaviour of human, animals, birds, fishes and mammals.

### 3.Methods

The OPF problem can be represented mathematically as  $F(x,u)$ , subjected to Equation 1 and Equation 2.

$$e(x,u) = 0 \quad (1)$$

$$ne(x,u) \leq 0 \quad (2)$$

$F$  is the optimized objective function focuses on minimum or maximum,  $x$  is a state variable set,  $u$  is a control variable set,  $e$  is set of equality constraints,  $ne$  is set of inequality constraints.

The state variables are real power at reference bus, voltage magnitude at load bus, reactive power(PV) at generator bus and apparent power through power lines. The control variables are real power at generator bus except reference bus, voltage magnitudes at generator bus, VAR compensators and transformer tap settings. The constraints are equality constraints and inequality constraints. The real and reactive power balance between generator and load bus are treated as equality constraints. The limits of real at generator bus, limits of voltage magnitudes at generator bus, limits of VAR compensators and limits of transformer tap settings are picked as inequality constraints in OPF problem.

State vector is modelled as shown in Equation 3.

$$x = [P_S, V_{NPQ}, Q_{NPV}, S_{NTL}^T] \quad (3)$$

$P_S$  is the real power at reference bus,  $V_{NPQ}$  is the load bus voltage,  $Q_{NPV}$  is the reactive power at generator bus,  $S_{NTL}$  is the apparent power in line,  $NPQ$  is the number of load bus,  $NPV$  is the number of generator bus,  $NTL$  is the total number of lines

Control vector is modelled as shown in Equation 4.

$$u = [P_{NPV}^T, V_{NPV}^T, Q_{NC}^T, T_{NT}^T] \quad (4)$$

$P_{NPV}$  is the real power at generator buses,  $V_{NPV}$  is voltage at generator bus,  $Q_{NC}$  is the shunt reactive power,  $T$  is the transformer tap settings,  $NC$  is the number of shunt compensators,  $NT$  is number of transformers.

### 3.1Objective functions

#### 3.1.1TFC

$$OF1 = \sum_{k=1}^{NPV} (a_k P_{PVk}^2 + b_k P_{PVk} + c_k) \quad (5)$$

$a_k, b_k, c_k$  are cost coefficients at generator  $k$ ,  $P_{PVk}$  is real power at  $k^{\text{th}}$  PV bus (Equation 5).

#### 3.1.2TAPL

$$OF2 = \sum_{k=1}^{NTL} \sum_{j=1}^{NTL} G_{jk} (V_j^2 + V_k^2 - 2V_j V_k \cos \delta_{jk}) \quad (6)$$

$G_{jk}$  is the conductance of line connected between  $j^{\text{th}}$  bus and  $k^{\text{th}}$  bus,  $\delta_{jk}$  is the voltage phase angle of line between bus  $j$  and bus  $k$  (Equation 6).

#### 3.1.3TVD

$$OF3 = \sum_{k=1}^{NPQ} |(V_{PQk} - 1)| \quad (7)$$

$V_{PQk}$  is voltage magnitude at  $k^{\text{th}}$  PQ bus (Equation 7)

#### 3.1.4VSI

$$OF4 = \min(\max(L_n)); n = 1, 2, \dots, NPQ \quad (8)$$

$$L_n = \left| 1 - \sum_k^{NPV} H_{jk} \frac{V_j}{V_k} \right| \quad j = 1, 2, \dots, NPQ \quad (9)$$

$H_{jk}$  is matrix obtained by partition inversion of  $Y_{BUS}$  between  $j^{\text{th}}$  PQ bus and  $k^{\text{th}}$  PV bus (Equation 8 and 9).

### 3.2Constraints

#### 3.2.1Equality constraints

$$P_{PVk} - P_{PQk} = |V_k| \sum_{j=1}^{NB} |V_j| (G_{kj} \cos \delta_{kj} + B_{kj} \sin \delta_{kj}) \quad (10)$$

$$Q_{PVk} - Q_{PQk} = |V_k| \sum_{j=1}^{BN} |V_j| (G_{kj} \sin \delta_{kj} - B_{kj} \cos \delta_{kj}) \quad (11)$$

$(P_{PVk} - P_{PQk})$  is the net real power at  $k^{\text{th}}$  bus,  $(Q_{PVk} - Q_{PQk})$  is the net reactive power at  $k^{\text{th}}$  bus,  $V_k$  and  $V_j$  are voltage magnitudes at  $k^{\text{th}}$  and  $j^{\text{th}}$  bus,  $G_{kj}$  is conductance between  $k^{\text{th}}$  and  $j^{\text{th}}$  bus,  $B_{kj}$  is the susceptance between  $k^{\text{th}}$  bus and  $j^{\text{th}}$  bus,  $\delta_{kj}$  is the voltage phase difference between  $k^{\text{th}}$  bus and  $j^{\text{th}}$  bus (Equation 10 and 11).

#### 3.2.2Inequality constraints

$$\text{PV bus constraints, Real power, } P_{PVk}^{\min} \leq P_{PVk} \leq P_{PVk}^{\max} \quad k \in NPV \quad (12)$$

$$\text{Voltage magnitude, } V_{PVk}^{\min} \leq V_{PVk} \leq V_{PVk}^{\max} \quad k \in NPV \quad (13)$$

$$\text{Reactive power, } Q_{PVk}^{\min} \leq Q_{PVk} \leq Q_{PVk}^{\max} \quad k \in NPV \quad (14)$$

$$\text{PQ bus constraints Voltage magnitude, } V_{PQk}^{\min} \leq V_{PQk} \leq V_{PQk}^{\max} \quad k \in NPQ \quad (15)$$

$$\text{Transmission lines constraints Transformer ratio, } T_k^{\min} \leq T_k \leq T_k^{\max} \quad k \in NT \quad (16)$$

$$\text{VAR compensator, } Q_{Ck}^{\min} \leq Q_{Ck} \leq Q_{Ck}^{\max} \quad k \in NC \quad (17)$$

$$\text{Apparent power, } S_{Lk} \leq S_{Lk}^{\max} \quad k \in NTL \quad (18)$$

$P_{PVk}^{\min}$  and  $P_{PVk}^{\max}$  is the lower and higher values of generators' real power at  $k^{\text{th}}$  bus,  $Q_{PVk}^{\min}$  and  $Q_{PVk}^{\max}$  is the lower and higher values of generators' reactive

power at  $k^{\text{th}}$  bus,  $V_{PVk}^{\min}$  and  $V_{PVk}^{\max}$  is the lower and higher values of generators' voltage magnitudes at  $k^{\text{th}}$  bus,  $V_{PQk}^{\min}$  and  $V_{PQk}^{\max}$  is the lower and higher values of loads' voltage magnitude at  $k^{\text{th}}$  bus,  $T_k^{\min}$  and  $T_k^{\max}$  is the lower and higher values of transformer tap setting ratio at  $k^{\text{th}}$  bus,  $Q_{Ck}^{\min}$  and  $Q_{Ck}^{\max}$  is the lower and higher values of VAR compensation at  $k^{\text{th}}$  bus,  $S_{Lk}^{\max}$  is maximum apparent power to be transmitted through  $k^{\text{th}}$  transmission line.

### 3.3 Improved mayfly algorithm (IMA)

Mayfly algorithm (MA) is proposed by Zervoudakis and Tsafarakis in 2020 [33] inspired through social behavior of mayflies. They derived the named as, the Mayflies appears only in the month of May in United Kingdom. MA is developed as hybrid algorithm with combination of PSO, FA and GA. GA is population based evolutionary method based on the Survival of Fittest concept of Darwin's theory introduced by Holland in 1960 and further analyzed by Goldberg in 1989 [34]. The solutions of GA are in the form of chromosomes. The chromosomes are updated by using genetic operators like crossover and mutation. The best solutions are obtained by replacing the worst solutions in the stages of selection, crossover and mutation. PSO is a population-based swarm intelligent method that is based on swarm behavior of fishes or birds introduced by Kennedy and Ebehart in 1995 [35] to solve the continuous optimization problem. The position of the particles in swarm represents the solution obtained by PSO in solution space. The current position of the particles is updated by adding velocity to the particle. The particle's velocity depends on the previous position of local and global. FA is also population-based swarm intelligent method that is based on the behavior of fireflies proposed by Yang in 2008 [36] to solve problems having continuous and discontinuous variables. The solution of FA depends on the variation in intensity of light and attractiveness. The fitness value of each firefly is related according to its stability to ejaculate brightness. The firefly with less intensity is attracted towards high intensity. The fireflies with same light intensity moves randomly. The best solution is obtained by updating the current position, attractiveness and random terms.

The proposed IMA is a nature inspired algorithm that has the advantages of evolutionary algorithm (GA) [37, 38], swarm intelligence algorithm (PSO) [39] and population-based algorithm (FA) [40–42]. The important steps involved in IMA are (i) Initialization, (ii) Updating of male mayflies, (iii) Updating of

female mayflies, (iv) Mating of male mayflies with female mayflies.

#### 3.3.1 Initialization

Initialize the positions and velocities of mayflies as given in Equation 19 to Equation 22.

$$x_i^m = [x_1^m, x_2^m, x_3^m, \dots, x_n^m] \quad (19)$$

$$v_i^m = [v_1^m, v_2^m, v_3^m, \dots, v_n^m] \quad (20)$$

$$x_i^f = [x_1^f, x_2^f, x_3^f, \dots, x_n^f] \quad (21)$$

$$v_i^f = [v_1^f, v_2^f, v_3^f, \dots, v_n^f] \quad (22)$$

$x_i^m$  is the positions of  $i^{\text{th}}$  male mayfly,  $x_i^f$  is the positions of  $i^{\text{th}}$  female mayfly,  $v_i^m$  is the velocities (change of positions) of  $i^{\text{th}}$  male mayfly,  $v_i^f$  is the velocities of  $i^{\text{th}}$  female mayfly.

#### 3.3.2 Updating of male mayfly

The updated velocity of male mayfly given by

$$\text{if } f(x_{ij}^m(t)) \geq \text{best}(p_{ij}^m), \quad v_{ij}^m(t+1) = g * v_{ij}^m(t) + a_1 e^{-\beta r_p^2} (p_{ij}^{\text{best}} - x_{ij}^m(t)) + a_2 e^{-\beta r_g^2} (g_j^{\text{best}} - x_{ij}^m(t)) \quad (23)$$

otherwise

$$v_{ij}^m(t+1) = v_{ij}^m(t) + d * r \quad (24)$$

$v_{ij}^m(t+1)$ - $i^{\text{th}}$  male mayfly velocity in  $j^{\text{th}}$  dimension during  $(t+1)^{\text{th}}$  iteration,  $v_{ij}^m(t)$ -  $i^{\text{th}}$  male mayfly velocity in  $j^{\text{th}}$  dimension during  $t^{\text{th}}$  iteration,  $x_{ij}^m(t+1)$ -  $i^{\text{th}}$  male mayfly position in  $j^{\text{th}}$  dimension during  $(t+1)^{\text{th}}$  iteration,  $x_{ij}^m(t)$ - $i^{\text{th}}$  male mayfly position in  $j^{\text{th}}$  dimension during  $t^{\text{th}}$  iteration,  $p_{ij}^{\text{best}}$  is the individual best position during  $(t+1)^{\text{th}}$  iteration,  $g_j^{\text{best}}$  is the global best position during  $t^{\text{th}}$  iteration,  $r_p$  is the Cartesian distance between individual and personal best,  $r_g$  is the Cartesian distance between individual and global best,  $g$  is the gravitational co-efficient,  $a_1$  and  $a_2$  are the positive attractive co-efficient,  $\beta$  is the fixed visible co-efficient,  $d$  is the nuptial co-efficient,  $r$  is the random number.

The personal best solution of male mayfly is given as,

$$p_{ij}^{\text{best}} = \begin{cases} x_{ij}^m(t+1), & \text{if } f(x_{ij}^m(t+1)) \leq f(p_{ij}^{\text{best}}) \\ x_{ij}^m(t), & \text{otherwise} \end{cases} \quad (25)$$

The global best position is given by

$$g_j^{\text{best}} = \min\{f(p_1^{\text{best}}), f(p_2^{\text{best}}), \dots, f(p_j^{\text{best}})\} \quad (26)$$

#### 3.3.3 Updating the female mayfly

The updated velocity of female mayfly given by

$$\text{if } f(x_{ij}^f(t)) \geq f(x_{ij}^m(t)) \quad v_{ij}^f(t+1) = g * v_{ij}^f(t) + a_2 e^{-\beta r_{mf}^2} (x_{ij}^m(t) - x_{ij}^f(t)) \quad (27)$$

otherwise

$$v_{ij}^f(t+1) = g * v_{ij}^f(t) + fl * r \quad (28)$$

$v_{ij}^f(t + 1)$ -i<sup>th</sup> female mayfly velocity in j<sup>th</sup> dimension during (t+1)<sup>th</sup> iteration,  $v_{ij}^f(t)$ - i<sup>th</sup> female mayfly velocity in j<sup>th</sup> dimension during t<sup>th</sup> iteration,  $x_{ij}^f(t + 1)$ - i<sup>th</sup> female mayfly position in j<sup>th</sup> dimension during (t+1)<sup>th</sup> iteration,  $x_{ij}^f(t)$ -i<sup>th</sup> female mayfly position in j<sup>th</sup> dimension during t<sup>th</sup> iteration,  $p_{ij}^{best}$  is the individual best position during (t+1)<sup>th</sup> iteration,  $r_{mf}$  is the distance in cartesian space between the male and female mayflies, fl is random walk coefficient.

**3.3.4 Mating of male mayflies with female mayflies**

Mating process is done through crossover and mutation. Simulated binary crossover and polynomial mutation is used to obtain better new solutions.

The simulated binary crossover [43] is implemented as

$$mf_{new}^1 = 0.5[(1 + \varepsilon) * v_{ij}^m(t) + (1 - \varepsilon) * v_{ij}^f(t)] \tag{29}$$

$$mf_{new}^2 = 0.5[(1 - \varepsilon) * v_{ij}^f(t) + (1 + \varepsilon) * v_{ij}^m(t)] \tag{30}$$

$$\varepsilon = \begin{cases} 2r^d \text{ if } r \leq 0.5 \\ \left[ \frac{1}{2(1-r)} \right]^d \text{ if } r > 0.5 \end{cases} \tag{31}$$

$$d = \frac{1}{(d_i + 1)} \tag{32}$$

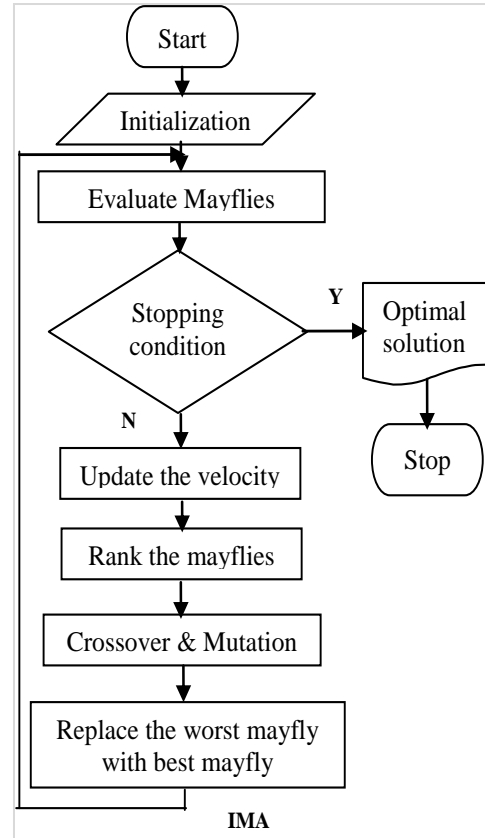

The polynomial mutation is implemented through

$$mf_{new}(t + 1) = mf_{new}(t) + \{mf_{new}^{max}(t) - mf_{new}^{min}(t)\} \sigma_m \tag{33}$$

$$\sigma_m = \begin{cases} 2r^{\frac{1}{m_i - 1}} - 1 & \text{if } r \leq 0.5 \\ 1 - 2(1 - r)^{\frac{1}{m_i + 1}} & \text{if } r > 0.5 \end{cases} \tag{33}$$

$m_i$  is the mutation index,  $d_i$  is the crossover index

The process of IMA is as follows: Initially, the positions and velocities of mayflies are assigned randomly. The objective function value of each mayfly is computed. After evaluating mayfly's fitness value, the stopping criteria need to be verified. If the stopping criteria is not met, then update the velocities of both mayflies i.e., male and female. Calculate the fitness of updated mayflies and sort the mayflies with high fitness value to low fitness value. Randomly separate the mayflies into male and female mayflies. Replace the worst mayfly with best mayfly and update individual best and global best value of fitness function. The process is repeated until the stopping criterion is achieved to obtain the optimal solutions. The flow chart of IMA is drawn in *Figure 1*.

**Figure 1** Flowchart related to improved mayfly algorithm (IMA)

The pseudo-code of IMA is given below:

- Start
- Set the positions and velocities of male mayflies
- Set the positions and velocities of female mayflies
- Configure the objective functions
- Measure the solutions
- While do stopping condition is not satisfied
  - Upgrade the velocities of mayflies
  - Upgrade the fitness values of mayflies
  - Measure the new solutions
  - Sort the mayflies in order
  - Apply crossover and mutation
  - Calculate the fitness of off-springs
  - Randomly partition the mayflies into two
  - Substitute the worst with best mayflies
  - Upgrade the pbest and gbest
- End while
- Obtain the optimal solution
- End

### 4.Results

The effectiveness of different algorithms such as IMA, GA, PSO and MA was tested on IEEE-30 bus system, 62-bus Indian utility system, IEEE-118 bus system. The performance of the EAs is investigated by considering optimal values and convergence rate. Performance metrics are taken into account for the

evaluation of EAs. The OPF problem is modelled and simulated in Laptop build with 8 GB RAM, AMD Ryzen V generation processor installed with 64-bit Windows 10 OS. The results are simulated in MATPOWER 7.0b with MATLAB 2016. The details of test systems are displayed in *Table 1*. The parameters of different EAs are given in *Table 2*.

**Table 1** Details of test system

Parameters	Test System-1	Test System-2	Test System-3
No. of bus	30	62	118
No. of branches	41	89	186
Total Generation Capacity	287.22 MW	2985.82 MW	4319.4 MW
	78.16 MVAR	680.09 MVAR	388.26 MVAR

	Crossover probability index	3			
Mutation probability index	18				

#### 4.1Test system-1: IEEE-30 bus system

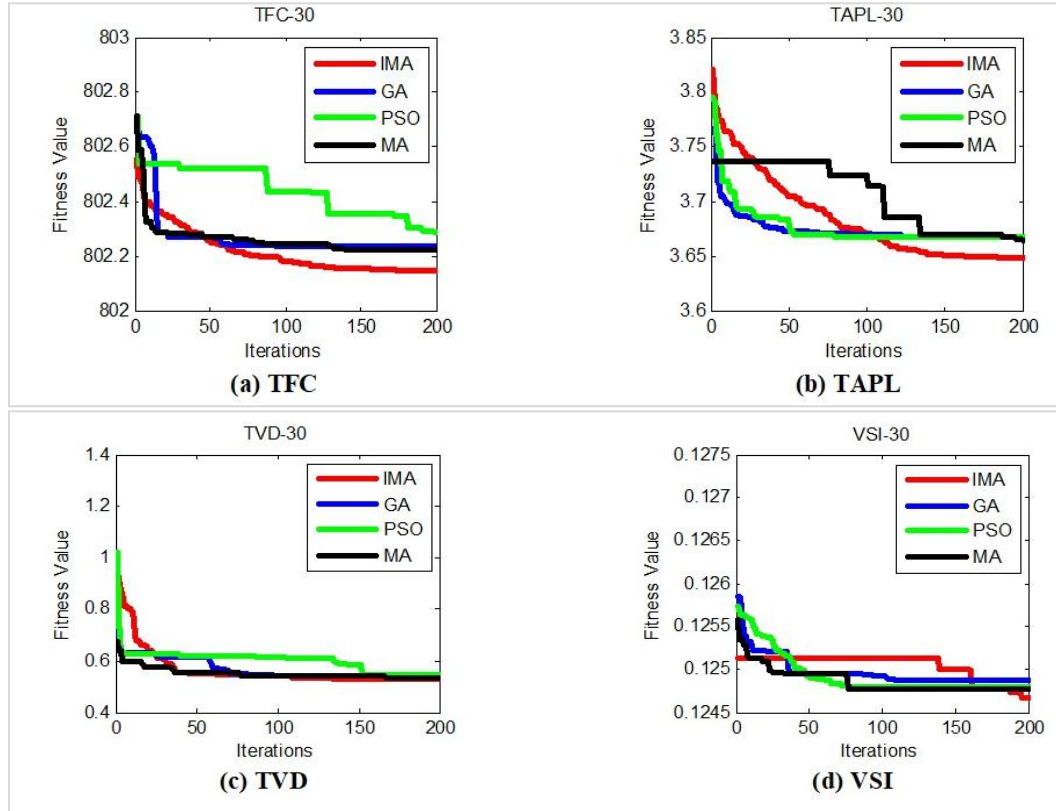

This test system consists of 25 control variables in which 6 are real power at various generator bus, 6 are voltage magnitudes at various generator bus, 4 are transformer tap settings and 9 are VAR compensators that minimize objective functions. The real power at PV bus is restricted between 10 MW and 200 MW. The voltage level at PV bus is bounded within 0.95 and 1.1p.u. The ratio of transformer tap settings is limited between 0.9 and 1.1p.u. The cutoff range of shunt compensators is (0, 5) MVAR. The convergence characteristics of Test system-1 for

different objective functions are shown in *Figure 2 (a)-(d)*. The values of variables to minimize TFC, TAPL, TVD, VSI for Test system-1 using IMA is tabulated in *Table 3*. The optimal solution attained by IMA for TFC is 802.1448 \$/hr, the TAPL is 3.6487 MW, TVD is 0.5279 pu and VSI is 0.1247. The comparison of optimal solution of objective functions with different EAs is listed in *Table 4*.

In comparison, the best optimal solution is achieved by implementing IMA for all objective functions. The worst optimal solution for TFC is 802.2899 \$/hr

with PSO, the TAPL is 3.6687 MW with GA, TVD is 0.5442 pu with PSO and VSI is 0.1249 with GA. The effectiveness of different EAs with each objective function is acknowledged with the performance

metrics that are indexed in *Table 5*. The statistical measures of optimal solution of EAs are pictured in *Figure 3(a)-(d)*.

**4.2 Test System-2: 62-bus Indian utility system**

The total number of control variables for the 62-bus Indian utility system is 49 in which 19 variables represent the real power at generator bus, another 19 variables represent voltage magnitudes at generator bus and the remaining 11 variables represent transformers' tap settings. The real power at PV

buses is restricted to the maximum value of 600 MW. The voltage level at PV bus is bounded between 0.9 and 1.1 p.u. The ratio of transformer tap settings is in the range of 0.9 and 1.1 p.u. The convergence characteristics of Test system-2 for different objective functions are shown in Figure 4 (a)-(d).

**Figure 4** Convergence curves of test system-2

The comparison of optimal solution of objective functions considering IMA, GA, PSO and MA is listed in *Table 6*. Based on comparison, it is evident that the optimal solution is achieved by implementing IMA for all objective functions. The worst optimal solution for TFC is 13309.6423 \$/hr with GA, TAPL is 75.6726 MW with PSO, TVD is 0.8946 pu with GA and VSI is 0.1004 with GA. The values of variables to minimize TFC, TAPL, TVD, VSI for

Test system-2 using IMA is tabulated in *Table 7*. The optimal solution attained by IMA for TFC is 13305.4267 \$/hr, the TAPL is 73.8746 MW, TVD is 0.8049 pu and VSI is 0.0986. The effectiveness of different EAs with each objective function is acknowledged with the performance metrics that are indexed in *Table 8*. The statistical measures of optimal solution of EAs are pictured in *Figure 5(a)-(d)*.

### 4.3 Test System-3: IEEE-118 bus system

This test system contains 129 control variables in which 54 are representing real power at generator bus, 54 are for voltage magnitudes at generator bus, 9 are for transformers tap settings and 12 are for shunt VAR compensators. The real power at PV bus is restricted to the maximum of 550 MW. The voltage level at PV bus is bounded within 0.96 and 1.1 p.u. The ratio of transformer’s tap settings is within 0.9

and 1.1 p.u. The cut-off range of shunt compensators is [0,40] MVAR.

The convergence characteristics of Test system-3 for different objective functions are shown in *Figure 6 (a)-(d)*. The optimal solution attained by IMA for TFC is 129611.5389 \$/hr, the TAPL is 76.5261 MW, TVD is 0.8632 p.u and VSI is 0.0611.

Figure 6 Convergence curves of test system-3

The comparison of optimal solution of objective functions considering various EAs is listed in *Table 9*. Based on comparison, it is clear that the optimal solution is achieved by implementing IMA for all objective functions is better. The worst optimal solution for TFC is 129631.5253 \$/hr with PSO, the TAPL is 76.7381 MW with PSO, TVD is 1.3193 pu with PSO and VSI is 0.0619 with PSO. The worst

optimal solution is obtained by implementing PSO for all objective functions. The effectiveness of different EAs with each objective function is acknowledged with the performance metrics that are indexed in *Table 10*. The statistical measures of optimal solution of EAs are pictured in *Figure 7 (a)-(d)*.

## 5. Discussions

From the simulated results, it is observed that MA has shown better performance than GA and PSO. By implementing simulated binary crossover and polynomial mutation operators in MA, the performance of the MA is once again improved. The crossover probability index is varied from 1 to 10 with step size of 1 and the mutation probability index is varied from 10 to 30 with step size of 2. It is observed that for crossover probability index at 3 and mutation probability index at 18, the obtained value gives the optimal solution of the OPF problem. For larger systems, the results obtained by GA and PSO have shown less effectiveness. The solution obtained through implementation of the IMA has given a better solution for both smaller as well as larger power systems. The performance of the evolutionary algorithms are evaluated and compared through the convergence characteristics as illustrated in *Figures 2, Figure 4, Figure 6*, the optimal solution as given in *Table 4, Table 7, Table 10* and statistical metrics viz., min (best), avg (mean), max (worst) values of each objective functions are tabulated in *Table 5, Table 7, Table 10*.

The limitation of the meta-heuristic algorithm is that for particular parameters only, the solution obtained by IMA is better than the other algorithms. If the parameters are varied then there is no surety for the best optimal solution. Thus, IMA requires fine tuning of parameters in order to get the best solution for OPF problem.

A complete list of abbreviations is shown in *Appendix I*.

## 6. Conclusion

In this paper, IMA, GA, PSO and MA are used to identify the solutions for solving the OPF problem by considering different objective functions. The best optimal solution is achieved by implementing IMA for all objective functions of the test systems. The OPF problem is investigated on three different systems. Based on the simulation results, it is observed that the IMA has performed better than GA, PSO, MA. The performance analysis is also carried

out in terms of convergence curves, optimal solution and statistic measures. IMA is improved by the replacement of crossover and mutation operator in MA. The operators implemented in IMA are simulated binary crossover and polynomial mutation instead of arithmetic crossover and random distribution mutation in MA. The crossover and mutation operators of GA increase the convergence rate in IMA. The updating of mayflies in the IMA is similar to the updating of particles in PSO, which moves towards to the global optimal point. The random walk of mayflies is similar to that of random movement of fireflies in FA. IMA is a successful, productive optimization tool for solving OPF problems in regulated electrical power system networks.

**Vijaya Bhaskar K** received his Bachelor of Technology in Electrical and Electronics Engineering from Sri Venkatesa Perumal College of Engineering and Technology affiliated to JNTUH in 2007. He received a Master of Technology in Electrical Power Engineering from Sreenivasa

Institute of Technology and Management Studies affiliated to JNTUA in 2010. At present, he is pursuing Ph.D from Vel Tech Rangarajan Dr Sagunthala R&D Institute of Science and Technology He has worked as Assistant Professor for 8 years and published 9 papers in national and international journals and conferences. His areas of interest are Soft Computing Techniques applied to Power Systems. Email: vijayk252@gmail.com

**Ramesh S** received his BE in Electrical and Electronics Engineering from Annamalai University, India in 2003 and ME in Power Systems Engineering from Anna University in 2005. He has been awarded his PhD in the Faculty of Electrical Engineering from Anna University, Chennai in

2012. He has more than 15 years of teaching experience in electrical and electronics engineering courses. He is a life member in ISTE and a member of IEEE. At present, he is serving as a Professor in the Department of Electrical and Electronics Engineering, Vel Tech Rangarajan Dr. Sagunthala R&D Institute of Science and Technology, Avadi, Chennai. His research interests include Softcomputing, Power System Operation and Control, Intelligent Controllers, Electric Vehicles and Smart Grid. Email: rameshsme@gmail.com

**Chandrasekar P** completed his Bachelor of Technology in Electrical and Electronics Engineering from Pondicherry Engineering College, Pondicherry in 1997, Master of Engineering in Power Systems Engineering from College of Engineering, Guindy, Anna University, Chennai in 2002, Ph.D degree in Electrical Engineering from Anna University, Chennai in 2013. He has more than 23 years of Teaching and Research Experience Since 1997. He published 35 research papers in various journals and conferences of National and International levels. He has achieved Six research grants from various funding bodies, namely DST, DRDO, CSIR, IEEE Madras section. Email: hodeee@veltech.edu.in

2012. He has more than 15 years of teaching experience in electrical and electronics engineering courses. He is a life member in ISTE and a member of IEEE. At present, he is serving as a Professor in the Department of Electrical and Electronics Engineering, Vel Tech Rangarajan Dr. Sagunthala R&D Institute of Science and Technology, Avadi, Chennai. His research interests include Softcomputing, Power System Operation and Control, Intelligent Controllers, Electric Vehicles and Smart Grid. Email: rameshsme@gmail.com

**Karunanithi K** graduated bachelor of engineering from the Institution of Engineers (India), Kolkata in Electrical Engineering in 2005. He obtained his Master of Engineering in Power Systems Engineering in 2009 from Anna University, Tirunelveli. He completed his PhD from Kalasalingam University, Srivilliputtur in 2016. He has more than 20 years of teaching experience in various institutions. At present, he is serving as a Professor in the Department of Electrical and Electronics Engineering, Vel Tech Rangarajan Dr. SagunthalaR&D Institute of Science and Technology, Avadi, Chennai. He is a life member in ISTE and IE(I) and a member in IET. His research interests include Electric Vehicles, Smart Grid and Micro Grid. Email: drkkarunanithi@veltech.edu.in

2012. He has more than 15 years of teaching experience in electrical and electronics engineering courses. He is a life member in ISTE and a member of IEEE. At present, he is serving as a Professor in the Department of Electrical and Electronics Engineering, Vel Tech Rangarajan Dr. Sagunthala R&D Institute of Science and Technology, Avadi, Chennai. His research interests include Softcomputing, Power System Operation and Control, Intelligent Controllers, Electric Vehicles and Smart Grid. Email: rameshsme@gmail.com

**Raja A** completed his BTech in Information Technology in 2007 from Dr. Sivanthi Aditanar College of Engineering, Tiruchendur. He completed his ME in Computer Science and Engineering in 2010 from Manonmaniam Sundaranar University, Tirunelveli. He completed his PhD in 2016 from Manonmaniam Sundaranar University, Tirunelveli. His areas of interest are Image Processing and Cryptography. He has more than 14 years of teaching experience. He has published 44 papers in international journals, 25 in international conferences and 12 in national conferences.

### Appendix 1

S. No.	Abbreviation	Description
1	ACDE	Adaptive Constraint Differential Evolution
2	AIS	Artificial Immune System
3	AMTPG-Jaya	Adaptive Multiple Teams Perturbation Guided Jaya Algorithm
4	BAAMOA	Boundary Assigned Animal Migration Optimization Algorithm
5	CFA	Cuttle Fish Algorithm
6	COA	Coyote Optimization Algorithm
7	CS-GWO	Cross Over Grey Wolf Optimizer
8	DBN	Deep Belief Network
9	DE	Differential Evolution
10	ESCA	Enhanced Sine Cosine Algorithm
11	FA	Firefly Algorithm
12	FAHSA-PSOEA	Fuzzy Adaptive Harmony Search Algorithm With Particle Swarm Optimization Differential Evolutionary Algorithm
13	GA	Genetic Algorithm
14	IHOA	Improved Heap Optimization Algorithm
15	IMA	Improved Mayfly Algorithm
16	LAA	Learning Augmented Approach
17	MA	Mayfly Algorithm
18	MACO	Modified Ant Colony Optimization
19	MPIO-COSR	Modified Pigeon Inspired Optimization Through Constraint Objective Sorting Rule
20	MRFO	Manta Ray Foraging Optimization
21	MVPA	Most Valuable Player Algorithm
22	NISSOA	Novel Improved Social Spider Optimization Algorithm
23	NOKHA	Novel Oppositional Krill Herd Algorithm
24	NR	Newton Raphson
25	NSCA	Novel Sine Cosine Algorithm
26	OPF	Optimal Power Flow
27	PSO	Particle Swarm Optimization
28	TAPL	Total Active Power Losses
29	TFC	Total Fuel Cost
30	TSA	Tree Seed Algorithm
31	TVD	Total Voltage Deviation
32	VSI	Voltage Stability Index
33	WEA	Water Evaporation Algorithm
